Computer-Aided Evaluation of Malignancy with MRI of the Breast

The use of computer-aided evaluation (CAE) is proposed to assist radiologists’ interpretation of contrast-enhanced magnetic resonance imaging (MRI) of the breast. MRI of the breast is suggested as an alternative or adjunct to mammography or other screening and diagnostic tests because of its high sensitivity in detecting breast lesions. However, it has a high false-positive rate because of the difficulty in distinguishing between benign and malignant lesions. MRI may be used to screen individuals at high genetic risk of breast cancer or to look for more extensive disease in individuals diagnosed with breast cancer who are eligible for breast-conserving surgery; it is also being studied to gauge the impact of cancer treatment. The CAE systems reviewed in this policy are intended to improve the specificity of MRI in detecting or measuring malignant tissue, while maintaining the generally high sensitivity of MRI. This could potentially reduce biopsy rates if it improves the ability to identify which MRI-detected lesions are almost certainly benign. There is anecdotal information that MRI may also be used in an effort to reduce re-operation rates among patients undergoing breast-conserving surgery by more clearly identifying the tissue that should be removed. The use of CAE may also shorten the time needed to interpret breast MRI images, which currently takes longer than reading mammograms.

CAE systems for MRI essentially provide easier ways of interpreting the patterns of contrast enhancement across a series of images, which in turn may help identify lesions and their likelihood of being malignant. Two key aspects of enhancement (also called kinetics) are examined: 1) within the first minute or so, does the lesion enhance up to a certain threshold (e.g., 50%, 100% of the initial value) and 2) what is the subsequent pattern of enhancement (continues to increase, plateaus, or declines [called "washout"])? In contrast to computer-aided detection (CAD) systems used with mammography, CAE for MRI is not aimed primarily at identifying lesions for consideration by a radiologist. Unlike the subtle appearance of lesions on mammography, most cancers enhance on MRI. The challenge is determining which lesions are benign and which are malignant. A large number of images are produced during MRI of the breast: images are taken at varying “depths” throughout each breast multiplied by the number of times the breast is imaged to capture different time points in the enhancement process; this can produce hundreds of images. Radiologists view the images to detect suspicious areas, and then they can pick a region of interest and look at the enhancement pattern. However, there may be variations across radiologists in the regions of interest selected and in the precise definition of the region of interest. CAE systems, in contrast, use color-coding and differences in hue to indicate the patterns of enhancement for each pixel in the breast image, thereby allowing the radiologist to analyze the enhancement patterns systematically.

CAE systems for MRI of the breast were initially called CAD systems, the same terminology used for mammography. However, the focus with MRI of the breast is on improving specificity (distinguishing malignant from benign) rather than increasing sensitivity (i.e., detection), as in mammography. The authors of 2 recent studies refer to CADStream as a computer-aided evaluation (CAE) program, and that terminology has been adopted in this policy.

Regulatory Status
Several CAE systems for use with MRI of the breast have 510(k) marketing clearance from the U.S. Food and Drug Administration (FDA). Some of these systems may have broader uses beyond breast MRI. There also may be some overlap in the functions performed by these devices and other image-processing systems.

- The 3TP (3 Time Point) Software Option, manufactured by 3TP LLC (now called CAD Sciences, White Plains, NY), was cleared on June 23, 2003. iCAD acquired CAD Sciences in 2008 and is now marketing a system called SpectraLook™ with CADVue™.
- CADstream™, which is manufactured by Confirma, Inc. (Kirkland, WA), was cleared on July 30, 2003; Merger Healthcare (Hartland, WI) subsequently acquired Confirma.
- Aegis™ (Sentinelle Medical Inc, Toronto, Ontario, Canada) received 510(k) marketing clearance from the FDA on February 9, 2007, as substantially equivalent to CADStream Version 4.0. However, in the 510(k) documents, the manufacturer states that the primary goal of Aegis is “to identify where and how deep a biopsy or localization needle should be inserted into an imaged breast.”
- DynaCAD® (MRI Devices Corporation, Waukesha, WI; now from Invivo Corp, Orlando, FL) was cleared July 21, 2004.
- Z3D Contrast Acuity Software (Clario Medical Imaging, Inc., Seattle, WA), which was cleared September 5, 2008, and is apparently used in conjunction with CAE for MRI systems.

According to documents filed with the FDA, the 3TP Software Option is “intended to be used as a post-processing software package designed to provide a reliable means for visualizing the presence and pattern of contrast-induced enhancement on MR datasets.” It provides a color-coded image that indicates the likelihood that each pixel shows malignant or benign tissue based on the changes in enhancement at 3 points in time, which are defined by the software program. CADstream is described as a “Computer Aided Detection (CAD) system intended for use in analyzing magnetic resonance imaging (MRI) studies. CADstream automatically registers serial patient image acquisitions to minimize the impact of patient motion, segments and labels tissue types based on enhancement characteristics (parametric image maps), and performs other user-defined post-processing functions (image subtractions, multiplanar reformats, maximum intensity projections). When interpreted by a skilled physician, this device provides information that may be useful in screening and diagnosis…Patient management should not be based solely on the results of the CADstream analysis.” It also provides automated determination of volumes of interest. In addition, CADstream can be used during MRI-guided biopsies.

***Note: This Medical Policy is complex and technical. For questions concerning the technical language and/or specific clinical indications for its use, please consult your physician.

Policy

The use of computer-aided evaluation (CAE) for interpretation of magnetic resonance imaging (MRI) of the breast is considered investigational. BCBSNC does not provide coverage for investigational services or procedures.

Benefits Application

This medical policy relates only to the services or supplies described herein. Please refer to the Member's Benefit Booklet for availability of benefits. Member's benefits may vary according to benefit design; therefore member benefit language should be reviewed before applying the terms of this medical policy.
Computer-Aided Evaluation of Malignancy with MRI of the Breast

**When Computer-Aided Evaluation of Malignancy with MRI of the Breast is covered**

Not applicable

**When Computer-Aided Evaluation of Malignancy with MRI of the Breast is not covered**

Computer-aided evaluation for interpretation of magnetic resonance imaging (MRI) of the breast is not covered.

**Policy Guidelines**

The available evidence consists primarily of retrospective studies that compare the accuracy of computer-aided MRI of breast malignancy versus conventional imaging. The populations in these studies are not representative of patients seen in clinical care; rather they include samples of individuals who are highly selected and usually have far more cases of cancer than would be encountered in a screening population. As a result, the true sensitivity and specificity of computer-aided MRI, and the incremental improvement in accuracy over conventional imaging, cannot be determined with certainty. Larger, well-designed, prospective studies are needed that include relevant clinical populations in order to determine whether computer-aided evaluation results in a clinically significant improvement in diagnostic accuracy. As a result of the deficiencies in the available literature, the use of computer-aided evaluation of malignancy with MRI is considered investigational.

**Billing/Coding/Physician Documentation Information**

This policy may apply to the following codes. Inclusion of a code in this section does not guarantee that it will be reimbursed. For further information on reimbursement guidelines, please see Administrative Policies on the Blue Cross Blue Shield of North Carolina web site at www.bcbsnc.com. They are listed in the Category Search on the Medical Policy search page.

*Applicable codes: 0159T*

This code would be used in addition to the code for breast MRI - 77058 – 77059

BCBSNC may request medical records for determination of medical necessity. When medical records are requested, letters of support and/or explanation are often useful, but are not sufficient documentation unless all specific information needed to make a medical necessity determination is included.
